International Conference Geometrical Methods in Mathematical Physics

A geometrical approach to testing integrability

Joseph Krasil'shchik (Independent Univ. of Moscow) in collaboration with Alik Verbovetsky (IUM) & Raf Vitolo (Univ. of Salento)

12-17 December 2011

Integrable structures

- (bi-)Hamiltonian structures,
- symplectic structures,
- recursion operators,

and infinite hierarchies of symmetries and/or conservation laws as a consequence.

Outline

- * Equations and solutions (basic notation)
- * Linearization and symmetries
- \star Conservation laws and cosymmetries
- * Nonlocal extensions (coverings)
- \star Tangent and cotangent coverings
- \star Recursion operators for symmetries
- ★ Symplectic structures
- * Hamiltonian structures
- * Recursion operators for cosymmetries
- ★ Computer support

Examples: the Korteweg-de Fries and Camassa-Holm equations.

Independent variables x^1, \ldots, x^n , unknown functions u^1, \ldots, u^m , the jet space $J^{\infty}(n,m)$ with the coordinates x^i , u^j_{σ} , $\sigma = i_1 \ldots i_{|\sigma|}$, $1 \le i_k \le n$. The projection $\pi_{\infty} \colon J^{\infty}(n,m) \to \mathbb{R}^n$ to the space of the independent variables.

The Cartan (higher contact) distribution & spans

$$D_i = \frac{\partial}{\partial x^i} + \sum_{j,\sigma} u^j_{\sigma i} \frac{\partial}{\partial u^j_{\sigma}},$$

the total derivatives. Dually, ${\mathscr C}$ annihilates

$$\omega_{\sigma}^{j} = du_{\sigma}^{j} - \sum_{i} u_{\sigma i} \, dx^{i}$$

(the Cartan, or higher contact, forms).

A differential equation (system)

$$F^{I}\left(\ldots,x^{i},\ldots,\frac{\partial^{|\sigma|}u^{j}}{\partial x^{\sigma}},\ldots\right)=0, \quad I=1,\ldots,r,$$

is identified with the hypersurface

$$\mathscr{E} = \{ D_{\sigma}(F^{\alpha}) = 0 \mid \alpha = 1, \dots, l, |\sigma| \ge 0 \} \subset J^{\infty}(n.m),$$

where $D_{\sigma} = D_{i_1} \circ \cdots \circ D_{\sigma_{|\sigma|}}$ (the infinite prolongation). The total derivatives can be restricted to \mathscr{E} and define the Cartan distribution there. Solutions are *n*-dimensional integral manifolds of this restriction.

Example: KdV For the KdV equation

 $u_t = uu_x + u_{xxx}$

coordinates on \mathscr{E} (internal coordinates) can be chosen as x, t, and $u_i = u_{X \dots X}$. The restricted total derivatives in these coordinates are

$$D_{x} = \frac{\partial}{\partial x} + \sum_{i} u_{i+1} \frac{\partial}{\partial u_{i}}, \qquad D_{t} = \frac{\partial}{\partial t} + \sum_{i} D_{x}^{i} (uu_{1} + u_{3}) \frac{\partial}{\partial u_{i}}.$$

The Cartan forms on \mathcal{E} are given by

$$\omega_i = du_i - u_{i+1} dx - D_x^i (uu_1 + u_3) dt, \qquad i = 0, 1, 2, \dots$$

Example: CH

For the Camassa-Holm equation

$$u_t - u_{txx} + 3uu_x = 2u_x u_{xx} + uu_{xxx}$$

the functions $u_l = \frac{\partial^l u}{\partial x^l}$, $u_{l,k} = \frac{\partial^{k+l} u}{\partial x^l \partial t^k}$, l = 0, 1, 2, $k \ge 1$, are taken as internal coordinates. Then

$$D_{x} = \frac{\partial}{\partial x} + \sum_{l=0}^{2} u_{l+1} \frac{\partial}{\partial u_{l}} + \sum_{k \ge 1} \left(u_{1,k} \frac{\partial}{\partial u_{0,k}} + u_{2,k} \frac{\partial}{\partial u_{1,k}} + D_{t}^{k}(u_{3}) \frac{\partial}{\partial u_{2,k}} \right),$$
$$D_{t} = \frac{\partial}{\partial t} + \sum_{l=0}^{2} u_{l,1} \frac{\partial}{\partial u_{l}} + \sum_{l=0}^{2} \sum_{k \ge 1} u_{l,k+1} \frac{\partial}{\partial u_{l,k}}$$

with $u_3 = (u_{0,1} - u_{2,1} + 3uu_1 - 2u_1u_2)/u$.

Symmetries and linearizations

A symmetry of the Cartan distribution is a π_{∞} -vertical vector field X that preserves \mathscr{C} . This amounts to

 $[X, D_i] = 0, \qquad i = 1, \dots, n.$

On $J^{\infty}(n,m)$ all symmetries are

$$\partial_{\varphi} = \sum_{\sigma,j} D_{\sigma}(\varphi^{j}) \frac{\partial}{\partial u_{\sigma}^{j}},$$

where $\varphi = (\varphi^1, \dots, \varphi^m)$ is a smooth function (the generating function, or characteristic). We identify ∂_{φ} with φ , and the commutator induces the bracket

$$\{ arphi_1, arphi_2 \} = artheta_{arphi_1}(arphi_2) - artheta_{arphi_2}(arphi_1)$$

(the Jacobi bracket).

Symmetries and linearizations

Given an equation \mathscr{E} , define its linearization as follows. For a vector function $F = (F^1, \dots, F^r)$ set

$$\ell_{F} = \begin{pmatrix} \sum_{\sigma} \frac{\partial F^{1}}{\partial u_{\sigma}^{1}} D_{\sigma} & \dots & \sum_{\sigma} \frac{\partial F^{1}}{\partial u_{\sigma}^{m}} D_{\sigma} \\ \dots & \dots \\ \sum_{\sigma} \frac{\partial F^{r}}{\partial u_{\sigma}^{1}} D_{\sigma} & \dots & \sum_{\sigma} \frac{\partial F^{r}}{\partial u_{\sigma}^{m}} D_{\sigma} \end{pmatrix}$$

Being an operator in total derivatives (a \mathscr{C} -differential operator), ℓ_F can be restricted to any \mathscr{E} . If $\mathscr{E} = \{F = 0\}$ we set $\ell_{\mathscr{E}} = \ell_F|_{\mathscr{E}}$. Then φ is a symmetry iff

$$\ell_{\mathscr{E}}(\pmb{arphi})=0, \qquad \pmb{arphi}=(\pmb{arphi}^1,\ldots,\pmb{arphi}^m), \quad \pmb{arphi}^j\in C^\infty(\mathscr{E}).$$

The Lie algebra of symmetries is denoted by $sym(\mathscr{E})$.

Symmetries and linearizations

Example: KdV

In the case of the KdV equation, symmetries are defined by

$$D_t(\varphi) = u_1 \varphi + u D_x(\varphi) + D_x^3(\varphi),$$

where $\varphi = \varphi(x, t, u, u_1, \dots, u_k)$.

Example: CH

For the Camassa-Holm equation, the linearization is

 $D_t(\varphi) - D_x^2 D_t(\varphi) - u D_x^3(\varphi) - 2u_1 D_x^2(\varphi)$ $+ (3u - 2u_2) D_x(\varphi) + (3u_1 - u_3)\varphi = 0.$

Horizontal *q*-forms are

$$\Lambda^q_h(\mathscr{E}) = \{ a \, dx^{i_1} \wedge \cdots \wedge dx^{i_q} \mid a \in C^{\infty}(\mathscr{E}) \};$$

the horizontal de Rham differential $d_h \colon \Lambda_h^q \to \Lambda_h^{q+1}$

$$d_h(a\,dx^{i_1}\wedge\cdots\wedge dx^{i_q})=\sum_i D_i(a)\,dx^i\wedge dx^{i_1}\wedge\cdots\wedge dx^{i_q}.$$

Conservation laws

$$\mathsf{CL}(\mathscr{E}) = \frac{\{ \omega \in \Lambda_h^{n-1} \mid d_h \omega = 0 \}}{\{ \omega \in \Lambda_h^{n-1} \mid \omega = d_h \theta, \ \theta \in \Lambda_h^{n-2} \}}.$$

How to compute?

Cosymmetries of \mathscr{E} are vector functions $\boldsymbol{\psi} = (\boldsymbol{\psi}^1, \dots, \boldsymbol{\psi}^r)$ satisfying $\ell^*_{\mathscr{E}}(\boldsymbol{\psi}) = 0$, where for a \mathscr{C} -differential operator $\Delta \colon V \to W$

$$\Delta^* \colon \hat{W} = \hom(W, \Lambda_h^n) \to \hat{V} = \hom(V, \Lambda_h^n)$$

is its formally adjoint defined by

$$\begin{pmatrix} \vdots & \\ \dots & \sum_{\sigma} a_{ij}^{\sigma} D_{\sigma} & \dots \\ \vdots & \end{pmatrix}^* = \begin{pmatrix} \vdots & \\ \dots & \sum_{\sigma} (-1)^{|\sigma|} D_{\sigma} \circ a_{ji}^{\sigma} & \dots \\ \vdots & \end{pmatrix}$$

and satisfying the Green formula

$$\langle \Delta(\mathbf{v}), \hat{\mathbf{w}} \rangle - \langle \mathbf{v}, \Delta^*(\hat{\mathbf{w}}) \rangle = d_h \omega, \qquad \omega \in \Lambda_h^{n-1}$$

The group of cosymmetries is denoted by $cosym(\mathscr{E})$.

From now on assume $\mathscr{E} = \{F = 0\}$ to satisfy regularity conditions:

- $\pi_{\infty}: \mathscr{E} \to \mathbb{R}^n(x^1, \dots, x^n)$ is a surjection (no functional relation);
- $F \in V$ is such that $G|_{\mathscr{E}} = 0$, $G \in W$, implies $G = \Delta(F)$ for some $\Delta \colon V \to W$.

Let $d_h \omega = 0$, $d_h \in \Lambda^{n-1}(\mathscr{E})$, and $\tilde{\omega} \in \Lambda^{n-1}(J^{\infty})$, $\tilde{\omega}|_{\mathscr{E}} = \omega$:

$$d_h\omega = \Delta(F), \qquad \Delta \colon V \to \Lambda^n$$

Then

$$\delta(\omega) = \Delta^*(1)|_{\mathscr{E}} \in \mathsf{cosym}(\mathscr{E})$$

is the generating section (characteristic) of ω . When

 $\nabla \circ \ell_{\mathscr{E}} = 0$ implies $\nabla = 0$

(no compatibility condition) the operator $\delta : \operatorname{CL}(\mathscr{E}) \to \operatorname{cosym}(\mathscr{E})$ is monomorphic and is the Euler operator in the evolutionary case.

Example: KdV

In this case, the defining equation for cosymmetries is

 $D_t(\psi) = uD_x(\psi) + D_x^3(\psi), \qquad \psi \in C^{\infty}(\mathscr{E}).$

If $\omega = X dx + T dt$ is a c.l. then

$$\delta(\boldsymbol{\omega}) = \sum_{i\geq 0} (-D_{\boldsymbol{x}})^i \left(\frac{\partial X}{\partial u_i}\right).$$

Example: CH

The defining equation for cosymmetries is

 $D_t(\psi) = D_x^2 D_t(\psi) + u D_x^3(\psi) + u_1 D_x^2(\psi) + (u_2 - 3u) D_x(\psi).$

A way to extend \mathscr{E} with a set of (finite or infinite) nonlocal variables w^1, w^2, \ldots by introducing

$$\tilde{D}_i = D_i + X_i, \qquad X_i = \sum_{\alpha} X_i^{\alpha} \frac{\partial}{\partial w^{\alpha}}, \qquad i = 1, \dots, n,$$

with the conditions

 $D_i(X_j) - D_j(X_i) + [X_i, X_j] = 0, \qquad 1 \le i \le j \le n.$

The variables w^{α} satisfy the covering equation $\tilde{\mathscr{E}}$.

Any \mathscr{C} -differential operator can be lifted from \mathscr{E} to $\tilde{\mathscr{E}}$.

To any conservation law there corresponds a covering.

Example: KdV

The covering

$$\tilde{D}_x = D_x + u \frac{\partial}{\partial w}, \qquad \tilde{D}_t = D_t + \left(\frac{u^2}{2} + u_2\right) \frac{\partial}{\partial w}$$

is associated to the conservation law $u dx + (u^2/2 + u_2) dt$. The covering equation is the pKdV $w_t = w_x^2/2 + w_{xxx}$.

Example: CH

The covering

$$\tilde{D}_x = D_x + (u - u_2) \frac{\partial}{\partial w}, \qquad \tilde{D}_t = D_t + \left(u u_2 + \frac{1}{2}u_1^2 - \frac{3}{2}u^2\right) \frac{\partial}{\partial w}$$

corresponds to the c.l. $(u - u_2) dx + (uu_2 + u_1^2/2 - 3u^2)/2 dt$.

Example: Δ -coverings

Consider \mathscr{C} -differential operators $\Delta \colon V \to W$, $\Delta' \colon V' \to W'$ and look for $A \colon V \to V'$ such that

for some *B* (i.e., $A: \ker \Delta \to \ker \Delta'$). Extend \mathscr{E} with

 $\Delta(w)=0$

and solve

 $\tilde{\Delta}'(\Phi) = 0.$

Then...

... solutions linear w.r.t. w_{σ}^{α} are in one-to-one correspondence with

$$\frac{\{A \mid B \circ \Delta = \Delta' \circ A\}}{\{A \mid A = A' \circ \Delta\}}$$

.

То

$$\Phi = \left(\dots, \sum_{\sigma\beta} a^{\sigma}_{\alpha\beta} w^{\beta}_{\sigma}, \dots \right)$$

there corresponds

$$A_{\Phi} = \begin{pmatrix} \vdots & \\ \dots & \sum_{\sigma} a^{\sigma}_{\alpha\beta} w^{\beta}_{\sigma} & \dots \\ \vdots & \end{pmatrix}.$$

Two important particular cases:

Tangent and cotangent coverings

 $\Delta = \ell_{\mathscr{E}}: \text{ the tangent covering. Holonomic sections } \phi: \mathscr{E} \to \mathscr{T} \mathscr{E}$ are symmetries.

Example: KdV

$$\mathcal{TE}: \begin{cases} u_t = uu_x + u_{xxx}, \\ q_t = u_x q + uq_x + q_{xxx}. \end{cases}$$

 $\Delta = \ell_{\mathscr{E}}^*: \text{ the tangent covering. Holonomic sections } \psi \colon \mathscr{E} \to \mathscr{T}^*\mathscr{E}$ are cosymmetries. $\mathscr{T}^*\mathscr{E}$ is always an Euler-Lagrange equation with $\mathscr{L} = p^1 F^1 + \dots + p^r F^r.$

Example: KdV

$$\mathcal{T}^{*}\mathscr{E}:\begin{cases} u_{t}=uu_{x}+u_{xxx},\\ p_{t}=up_{x}+p_{xxx}. \end{cases}$$

Tangent and cotangent coverings

Example: CH

This is how the tangent and cotangent coverings look for the Camassa-Holm equation:

$$\mathscr{TE}: \begin{cases} u_t - u_{txx} + 3uu_x = 2u_x u_{xx} + uu_{xxx}, \\ q_t = q_{xxt} + uq_{xxx} + 2u_x q_{xx} - (3u - 2u_{xx})q_x - (3u_x - u_{xxx})q_x \end{cases}$$

and

$$\mathscr{T}^{*}\mathscr{E}: \begin{cases} u_{t}-u_{txx}+3uu_{x}=2u_{x}u_{xx}+uu_{xxx},\\ p_{t}=p_{xxt}+up_{xxx}+u_{x}p_{xx}+(u_{xx}-3u)p_{x}. \end{cases}$$

Nonlocal forms and vectors

Let $\varphi \in \text{sym}(\mathscr{E})$ and $\tilde{\varphi}$ be a vector function on J^{∞} such that $\tilde{\varphi}|_{\mathscr{E}} = \varphi$. Then

 $\langle \ell_{\mathcal{F}}(ilde{arphi}), {p}
angle - \langle ilde{arphi}, \ell_{\mathcal{F}}^*({p})
angle = d_h(\omega_{ ilde{arphi}}), \qquad \omega_{ ilde{arphi}} \in \Lambda_h^{n-1}.$

Then a canonical correspondence arises

 $v \colon \operatorname{sym}(\mathscr{E}) \to \operatorname{\mathsf{CL}}(\mathscr{T}^*\mathscr{E}), \qquad \varphi \mapsto \omega_{\widetilde{\varphi}} \Big|_{\mathscr{T}^*\mathscr{E}}.$

In a similar way, one has

 v^* : cosym $(\mathscr{E}) \to \mathsf{CL}(\mathscr{TE}).$

Elements $v(\phi)$, $v^*(\psi)$ are called nonlocal vectors and forms, resp.

Nonlocal forms and vectors Example: KdV

$$\upsilon(\varphi) = p\varphi \, dx + (up\varphi - 3p_x D_x(\varphi) + D_x^2(p\varphi)) \, dt,$$

$$\upsilon^*(\psi) = p\psi \, dx + (up\psi - 3p_x D_x(\psi) + D_x^2(p\psi)) \, dt.$$

Example: CH

$$\begin{split} \upsilon(\varphi) &= (\varphi - D_x^2(\varphi))p \, dx \\ &+ (((u_2 - 3u)\varphi + u_1 D_x(\varphi) + u D_x^2(\varphi))p - u D_x(\varphi)p_1 \\ &+ u \varphi p_2 - D_x(\varphi)p_{0,1} + \varphi p_{1,1}) \, dt, \\ \upsilon^*(\psi) &= (\psi - D_x^2(\psi))q \, dx \\ &+ (((u_2 - 3u)\psi + u D_x^2(\psi))q + (u_1\psi - u D_x(\psi))q_1 \\ &+ u \psi q_2 - D_x(\psi)q_{0,1} + \psi q_{1,1}) \, dt. \end{split}$$

On *TE*

Due to the general properties of Δ -coverings, solutions of $\tilde{\ell}_{\mathscr{E}}(\Phi) = 0$ lead to the operators \mathscr{R} :

while solving $\tilde{\ell}^*_{\mathscr{E}}(\Psi) = 0$ we obtain the operators \mathscr{S} satisfying

Solving equation

 $\tilde{\ell}_{\mathscr{E}}(\Phi) = 0$

in the tangent covering for Φ linear in q_{σ}^{j} we obtain operators \mathscr{R}_{Φ} : sym $(\mathscr{E}) \to sym(\mathscr{E})$.

Example: The heat eq.

For the heat equation the tangent covering is

$$u_t = u_{xx}, \qquad q_t = q_{xx}$$

with

$$\tilde{D}_{x} = \frac{\partial}{\partial x} + \sum_{i \ge 0} \left(u_{i+1} \frac{\partial}{\partial u_{i}} + q_{i+1} \frac{\partial}{\partial q_{i}} \right),$$
$$\tilde{D}_{t} = \frac{\partial}{\partial t} + \sum_{i \ge 0} \left(u_{i+2} \frac{\partial}{\partial u_{i}} + q_{i+2} \frac{\partial}{\partial q_{i}} \right).$$

Example: The heat eq. (continuation) Solving $\tilde{D}_t(\Phi) = \tilde{D}_v^2(\Phi)$

for

$$\Phi = a^0 q + a^1 q_1$$

we get

$$\Phi_{00} = q, \qquad \Phi_{10} = q_1, \qquad \Phi_{11} = tq_1 + \frac{2}{2}.$$

v

The corresponding operators are

$$\mathscr{R}_{00} = \mathrm{id}, \qquad \mathscr{R}_{10} = D_{\mathrm{x}}, \qquad \mathscr{R}_{11} = tD_{\mathrm{x}} + \frac{x}{2},$$

and they generate the entire algebra of recursion operators (which is isomorphic to the universal enveloping of the 3-dim Heisenberg algebra).

The next two examples need to extend \mathscr{TE} by nonlocal forms. Example: KdV

Consider the cosymmetry $1 \in cosym(\mathscr{E})$ and the conservation law

$$v^*(1) = q \, dx + (uq + q_2) \, dt$$

on \mathscr{TE} with the corresponding nonlocal variable

$$\frac{\partial Q^1}{\partial x} = q, \qquad \frac{\partial Q^1}{\partial t} = uq + q_2.$$

Then the equation $\tilde{\ell}_{\mathscr{E}}(\Phi)$ has two nontrivial solutions of the form $\Phi = A_1 Q^1 + a^0 q + a^1 q_1 + \dots + a^k q_k$:

$$\Phi_0 = q, \qquad \Phi_2 = q_2 + \frac{2}{3}uq + u_1\frac{1}{3}Q^1.$$

Example: KdV (continuation) The Lenard recursion operator

$$\mathscr{R} = D_x^2 + \frac{2}{3}u + \frac{1}{3}u_1 D_x^{-1}$$

corresponds to the second solution. Adding another nonlocal form

$$v^*(u) = qu dx + (qu^2 + q_2u - q_1u_1 + qu_2) dt,$$

leads to the operator

$$D_x^4 + \frac{4}{3}uD_x^2 + 2u_1D_x + \frac{4}{9}(u^2 + 3u_2) + \frac{1}{3}(uu_1 + u_3)D_x^{-1} + \frac{1}{9}u_1D_x^{-1} \circ u$$

which is \mathscr{R}^2 .

Example: CH

Let us extend \mathscr{TE} with the nonlocal form Q^1 associated with $\psi = 1$. Then $\tilde{\ell}_{\mathscr{E}}(\Phi) = 0$ has a solution

$$\Phi = q_{1,1} + q_2 u + q_1 u_1 + q(u_2 - 2u) - Q^1 u_1$$

with the corresponding recursion operator

$$\mathscr{R} = D_{x}D_{t} + uD_{x}^{2} + u_{1}D_{x} + (u_{2} - 2u) - u_{1}D_{x}^{-1}.$$

Given two recursion operators $\mathscr{R}_1,\mathscr{R}_2\colon$ sym $\mathscr{E}\to\mathscr{E},$ their Nijenhuis bracket

$$\llbracket \mathscr{R}_1, \mathscr{R}_2 \rrbracket$$
: sym $\mathscr{E} \times$ sym $\mathscr{E} \to$ sym \mathscr{E}

is defined by

$$\begin{split} \llbracket \mathscr{R}_1, \mathscr{R}_2 \rrbracket (\varphi_1, \varphi_2) &= \{ \mathscr{R}_1(\varphi_1), \mathscr{R}_2(\varphi_2) \} + \{ \mathscr{R}_2(\varphi_1), \mathscr{R}_1(\varphi_2) \} \\ &- \mathscr{R}_1(\{ \mathscr{R}_2(\varphi_1), \varphi_2 \} + \{ \varphi_1, \mathscr{R}_2(\varphi_2) \}) \\ &- \mathscr{R}_2(\{ \mathscr{R}_1(\varphi_1), \varphi_2 \} + \{ \varphi_1, \mathscr{R}_1(\varphi_2) \}) \\ &+ (\mathscr{R}_1 \circ \mathscr{R}_2 + \mathscr{R}_2 \circ \mathscr{R}_1) \{ \varphi_1, \varphi_2 \}. \end{split}$$

When \mathscr{R} is hereditary, i.e., $[\![\mathscr{R}, \mathscr{R}]\!] = 0$ and \mathscr{R} is invariant w.r.t. a symmetry φ , the symmetries $\varphi_i = \mathscr{R}^i(\varphi)$ form a commuting hierarchy.

Solving the equation $\tilde{\ell}^*_{\mathscr{C}}(\Psi) = 0$ on the tangent covering for Ψ linear in q^j_{σ} leads to operators

 $\mathscr{S}: \operatorname{sym}(\mathscr{E}) \to \operatorname{cosym}(\mathscr{E}).$

Let $\omega_1, \omega_2 \in \mathsf{CL}(\mathscr{E})$ be such that

$$\delta \omega_i = \mathscr{S} arphi_i, \qquad arphi_i \in \mathsf{sym}(\mathscr{E}).$$

Define

$$\{\omega_1, \omega_2\}_{\mathscr{S}} = L_{\mathscr{D}_{\varphi_1}}(\omega_2).$$

This bracket is skew-symmetric if $\ell_{\mathscr{C}}^* \circ \mathscr{S}$ is self-adjoint, i.e.,

$$\mathscr{S}^* \circ \ell_{\mathscr{E}} = \ell_{\mathscr{E}}^* \circ \mathscr{S}$$

(in the evolutionary case this amounts to $\mathscr{S}^* = -\mathscr{S}$). Then...

... for any $\boldsymbol{\varphi} = (\boldsymbol{\varphi}^1, \dots, \boldsymbol{\varphi}^m)$ on the ambient J^{∞}

$$\mathscr{S}^*\ell_F(\varphi) - \ell_F^*\mathscr{S}(\varphi) = \bar{\Delta}_{\varphi}(F)$$

for some $\overline{\Delta}_{\varphi} \colon W \to \hat{V}$. Set $\Delta_{\varphi} = \overline{\Delta}_{\varphi} |_{\mathscr{E}}$ and define $\delta \mathscr{S} \colon \operatorname{sym}(\mathscr{E}) \times \operatorname{sym}(\mathscr{E}) \to \operatorname{cosym}(\mathscr{E})$

by

$$(\delta \mathscr{S})(\varphi_1, \varphi_2) = (\Im_{\varphi_1} \mathscr{S})(\varphi_2) - (\Im_{\varphi_2} \mathscr{S})(\varphi_1) + \Delta^*_{\varphi_2}(\varphi_1).$$

Then

$$\delta \mathscr{S} = 0$$

guarantees that $\{\cdot, \cdot\}_{\mathscr{S}}$ satisfies the Jacobi identity. The \mathscr{S} is called a symplectic structure.

Example: KdV Solving $\tilde{\ell}^*_{\mathscr{E}}(\Psi) = 0$ for

$$\Psi = A_3 Q^3 + A_1 Q^1 + a^0 q + a^1 q_1 + \dots + a^k q_k$$

in \mathscr{TE} extended by nonlocal forms Q^1 , Q^3 , we get two solutions

$$\Psi_1 = Q^1, \qquad \Psi_3 = q_1 + \frac{1}{3}uQ^1 + \frac{1}{3}Q^3,$$

to which the symplectic operators

$$\mathscr{S}_1 = D_x^{-1}, \qquad \mathscr{S}_3 = D_x + \frac{1}{3}uD_x^{-1} + \frac{1}{3}D_x^{-1} \circ u$$

correspond.

Example: CH Solving $\tilde{\ell}^*_{\mathscr{E}}(\Psi) = 0$ in $\mathscr{T}\mathscr{E}$ extended by Q^1 , we get

 $\Psi=Q^1,$

i.e.,

$$\mathscr{S}_1 = D_x^{-1}.$$

After adding Q^3 (that corresponds to $\psi = u$) to the extension a new solution

$$\Psi = q_{0,1} + q_1 u - Q^3 - Q^1 u$$

arises with the corresponding symplectic structure

$$\mathscr{S}_3 = D_t + uD_x - D_x^{-1} \circ (u - u_2) - uD_x^{-1}.$$

We pass now to $\mathscr{T}^*\mathscr{E}$:

By the general properties of Δ -coverings, solutions of $\tilde{\ell}_{\mathscr{E}}(\Phi) = 0$ lead to the operators \mathscr{H} :

$$\begin{array}{ccc}
\hat{W} & \stackrel{\ell_{\mathcal{E}}^{*}}{\longrightarrow} \hat{V} \implies & \mathcal{H} : \ker \ell_{\mathcal{E}}^{*} \to \ker \ell_{\mathcal{E}} \\
 & \mathcal{H} & \downarrow B \\
 & V \stackrel{\ell_{\mathcal{E}}}{\longrightarrow} W,
\end{array}$$

while solving $\tilde{\ell}^*_{\mathscr{E}}(\Psi) = 0$ we obtain the operators \mathscr{S} satisfying

$$\begin{array}{ccc}
\hat{W} & \stackrel{\ell_{\mathscr{E}}^{*}}{\longrightarrow} \hat{V} \implies & \overline{\mathscr{R}} \colon \ker \ell_{\mathscr{E}}^{*} \to \ker \ell_{\mathscr{E}}^{*} \\
\bar{\mathscr{R}} & & \downarrow_{B} \\
\hat{W} & \stackrel{\ell_{\mathscr{E}}^{*}}{\longrightarrow} \hat{V}.
\end{array}$$

Consider solutions of $\tilde{\ell}_{\mathscr{E}}(\Phi) = 0$ linear in p_{σ}^{j} . They lead to operators

 $\mathscr{H}: \operatorname{cosym}(\mathscr{E}) \to \operatorname{sym}(\mathscr{E}).$

With such an operator, define the bracket

 $\{\omega_1, \omega_2\}_{\mathscr{H}} = L_{\mathscr{H}(\delta\omega_1)}(\omega_2)$

on $CL(\mathscr{E})$. The bracket is skew-symmetric if

 $\mathscr{H}^* \circ \ell_{\mathscr{E}}^* = \ell_{\mathscr{E}} \circ \mathscr{H}$

(for an evolutionary \mathscr{E} this is equivalent to $\mathscr{H}^* = -\mathscr{H}$). For any two operators $\mathscr{H}_1, \mathscr{H}_2: \operatorname{cosym}(\mathscr{E}) \to \operatorname{sym}(\mathscr{E})$ satisfying the above condition define their Schouten bracket

 $\llbracket \mathscr{H}_1, \mathscr{H}_2 \rrbracket \colon \mathsf{cosym}(\mathscr{E}) \times \mathsf{cosym}(\mathscr{E}) \to \mathsf{sym}(\mathscr{E})$

by

$$\begin{split} \llbracket \mathscr{H}_1, \mathscr{H}_2 \rrbracket (\psi_1, \psi_2) &= \mathscr{H}_1(\mathcal{L}_{\mathscr{H}_2\psi_1}(\psi_2)) - \mathscr{H}_2(\mathcal{L}_{\mathscr{H}_1\psi_1}(\psi_2)) \\ &+ \{\mathscr{H}_1(\psi_2), \mathscr{H}_2(\psi_1)\} - \{\mathscr{H}_1(\psi_1), \mathscr{H}_2(\psi_2)\}, \end{split}$$

where $\{\cdot, \cdot\}$ is the Jacobi bracket and

 $L_{\varphi}(\psi) = \Im_{\varphi}(\psi) + \ell_{\varphi}^{*}(\psi).$

The above bracket on $CL(\mathscr{E})$ enjoys the Jacobi identity if

 $\llbracket \mathscr{H}, \mathscr{H} \rrbracket = 0;$

 \mathscr{H} is called a Hamiltonian operator in this case and two Hamiltonian operators are compatible if $[\mathscr{H}_1, \mathscr{H}_2] = 0$. Then the Magri scheme can be applied to generate commutative hierarchies.

Example: KdV Solve the equation

 $\tilde{D}(\Phi) = u_1 \Phi + u \tilde{D}_x(\Phi) + \tilde{D}_x^3(\Phi), \qquad \Phi = a^0 p + a^1 p_1 + \dots + a^k p_k,$

leads to two nontrivial solutions

$$\Phi_1 = p_1, \qquad \Phi_3 = p_3 + \frac{2}{3}up_1 + \frac{1}{3}u_1p_0$$

with the corresponding (and well known) Hamiltonian operators

$$\mathscr{H}_1 = D_x, \qquad \mathscr{H}_3 = D_x^3 + \frac{2}{3}uD_x + \frac{1}{3}u_1.$$

Consider the x-translation u_x of the KdV and the corresponding nonlocal vector P^1 defined by

Example: KdV (continuation)

$$\frac{\partial P^1}{\partial x} = pu_x, \qquad \frac{\partial P^1}{\partial t} = p(uu_1 + u_3) + p_2u_1 - p_1u_2.$$

Then one obtains a new solution

$$\Phi_5 = p_5 + \frac{4}{3}up_3 + 2u_1p_2 + \frac{4}{9}(u^2 + 3u_2)p_1 + \left(\frac{4}{9}uu_1 + \frac{1}{3}u_3\right)p - \frac{1}{9}u_1P_1$$

in the extended setting to which the nonlocal Hamiltonian structure

$$\mathcal{H}_{5} = D_{x}^{5} + \frac{4}{3}uD_{x}^{3} + 2u_{1}D_{x}^{2} + \frac{4}{9}(u^{2} + 3u_{2})D_{x} + \left(\frac{4}{9}uu_{1} + \frac{1}{3}u_{3}\right) - \frac{1}{9}u_{1}D_{x}^{-1} \circ u_{1}$$

corresponds.

Example: CH In $\mathscr{T}^*\mathscr{E}$, the equation $\tilde{\ell}_{\mathscr{E}}(\Phi) = 0$ has two solutions

 $\Phi_1 = p_1, \qquad \Phi_3 = p_{0,1} + p_1 u - p u_1,$

to which there correspond two compatible Hamiltonian operators

$$\mathscr{H}_1 = D_x, \qquad \mathscr{H}_3 = D_t + uD_x - u_1,$$

Extending $\mathscr{T}^*\mathscr{E}$ by the nonlocal form $P^1 = \upsilon(u_1)$, we obtain the third, nonlocal operator

$$\mathscr{H}_{5} = u_{1}D_{x}^{-1} \circ \frac{2u_{1}u_{2} + u_{2,1} - 2uu_{1} - u_{0,1}}{u} - uD_{x}^{2}D_{t} - D_{x}D_{t}^{2}$$
$$+ uD_{t} - u_{0,1}D_{x}^{2} + u(-u + u_{2})D_{x} - 4uu_{1} + uu_{3} + 3u_{1}u_{2} + u_{2,1}.$$

Finally, solving the equation $\tilde{\ell}^*_{\mathscr{E}}(\Psi) = 0$ in the cotangent covering, one gets operators that take $\operatorname{cosym}(\mathscr{E})$ to itself, i.e., recursion operators for cosymmetries.

Example: KdV

The equation

$$\tilde{D}_t(\Psi) = u \tilde{D}_x(\Psi) + \tilde{D}_x^3(\Psi)$$

in $\mathscr{T}^*\mathscr{E}$ extended by P^1 gives

$$\Psi = p_2 + \frac{2}{3}up - \frac{1}{3}P^1$$

to which the recursion operator

$$\bar{\mathscr{R}} = D_x^2 + \frac{2}{3}u - \frac{1}{3}D_x^{-1} \circ u_1$$

corresponds.

Example: CH

In $\mathscr{T}^*\mathscr{E}$ extended by P^1 the equation $\tilde{\ell}^*_{\mathscr{E}}(\Psi)=0$ leads to the operator

$$\bar{\mathscr{R}} = D_x D_t + u D_x^2 - 2u + u_2 + D_x^{-1} \circ \frac{2u_1 u_2 + u_{2,1} - 2u u_1 - u_{0,1}}{u}.$$

All computations were done using CDIFF, a REDUCE package for computations in geometry of differential equations initially developed at the University of Twente (Paul Kersten, Peter Gragert, Marcel Roelofs) and upgraded later by Raffaele Vitolo, University of Salento. See http://gdeq.org.
